PROJECT WORK SAMPLE | EDITED FOR RECRUITMENT
Digital Voting
Jordan Smart Elections | Election process design and pilot planning

Design challenge:

How could digital counting and reporting tools support transparent election processes while preserving paper records, manual verification and accountable oversight?

My documented design contribution:

I developed concept documents, a proposed technical architecture, election-day scenarios and a phased pilot approach. I also prepared outreach materials and communicated the concept through institutional correspondence and LinkedIn posts.
:

Selected pilot design structure:

Pilot element	Proposed workflow	Control or verification
Paper ballots	Hand-marked ballots retained as the authoritative record	Secure custody and availability for recounts
Optical counting	Scanning and preliminary digital tally	Investigate unclear marks and compare with manual counts
Result consolidation	Restricted tally records and aggregate reporting	Access controls, logs and discrepancy records
Pilot evaluation	Simulations and approved internal election trials	Manual fallback, documented errors and participant feedback

Two proposals are documented: a wider smart-election vision prepared for party presentation, and a bounded paper-based pilot concept. The latter excludes online ballot casting; advanced AI and cryptographic options in the wider vision remain untested proposals.

Professional relevance:

Demonstrates project design, technical requirements coordination, process documentation, pilot planning and institutional communication.

Current evidence boundary:

Concept development, technical documentation and outreach. A deployed election system, completed pilot, independently tested security and approval for public elections have not been established.
The table summarises proposed pilot procedures, not completed trials. Outreach does not establish endorsement or partnership. No claim of absolute security, fraud prevention or verified counting accuracy is made.
